Furthermore, because signaling in the brain is communicated via the hippocampus, hypothalamus, and neocortex, we hypothesized that CA1 pyramidal neurons from the pyramidal lobe of the epileptic brain may be more susceptible to enhanced Wnt signaling because they receive innervation from local and long-range projecting projections which comprise the limbic system, where Wnt signaling can exert its effects. Moreover, CA1 pyramidal neurons are more vulnerable to glutamate-induced cell death compared to CA3 and dentate gyrus neurons, and the reduction of glutamate-evoked neurotoxicity in presymptomatic TG mice suggests a potential mechanism in the phenotypic development of the epilepsy. Finally, PSC and electrophysiological analyses strongly suggest the possibility that functional and structural modifications in CA1 pyramidal neurons may be more easily generated in comparison to CA3 pyramidal neurons in TG and KA mice due to their more immature neurogenesis, but these data need to be confirmed by analyses of the complete hippocampal circuit. In conclusion, the present study provides evidence that Wnt3a contributes to the development of epilepsy by enhancing cell survival, and by increasing synaptic plasticity and excitability in CA1 pyramidal neurons. Conclusions {#
