 instrumentsQ: Determining the
 TAC(k) of a CMAC? This
 question refers to the TAC(k)
 of a

$$\text{\operatorname{CMAC}}_k(L)$$

$$=$$

$$E(k)[\text{\operatorname{CAME}}_k(L)]$$
 where $E(k)$ is a block
 cipher with block size k , and

L is the MAC secret key. I am looking for a way to determine this value without brute force attack. In other words, is there a known equation that yields the $TAC(k)$ value? A: Yes, there is a known way. Let the MAC be represented by a binary matrix, C , of size $k \times \ell$, where k is the block size of the MAC and ℓ is the length of the MAC output. Let $C_{\{i,j\}}$ represent the i 'th row of C containing the j 'th output bit. In the

following I'll assume that ℓ is a multiple of k . We will define a binary function, $f(i,j)$, of the value of the i 'th row and j 'th column of C . For every row and every column, the function is a bit. Let $g_k(i,j)$ be the function that rotates the value of the i 'th row of C left by k positions. That is, if $C_{\{i,j\}} = 0$, $g_k(i,j)$ outputs 1; if C
